

2.1 Conditional Probability.

Notation "Suppress" probability measure space (Ω, \mathcal{A}) .

e.g) $P =$ A probability measure P on Ω with σ -algebra \mathcal{A} .

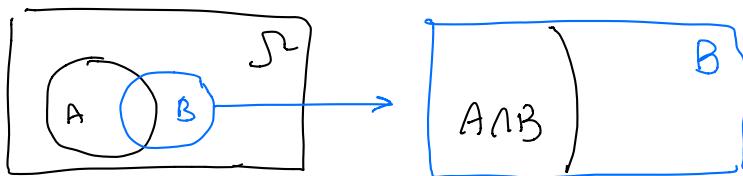

Note Very often, it doesn't matter what underlying measure space is, it only matters what P looks like in the events we're interested in.

Terminology Event = measurable set = set in σ -algebra \mathcal{A} .

Sample space = Ω .

Def. Conditional Probability of A given B .

If $P(B) > 0$, then $P(A|B) = \frac{P(A \cap B)}{P(B)}$.

2.2-3 Independence

"A fantastically useful property to have".

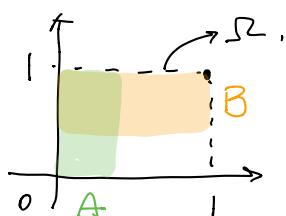

Def. (These are definitions used in different contexts, but not equivalent).

i) Independence for 2 events.

Events A and B are independent if $P(A \cap B) = P(A)P(B)$

Intuition A and B are not related \rightarrow ex) coinflip & dice roll.

Example

Probability of the overlap is the product of probabilities of individual events

ii) Independence of multiple events

Finite set of events A_1, A_2, \dots, A_n are (mutually) independent

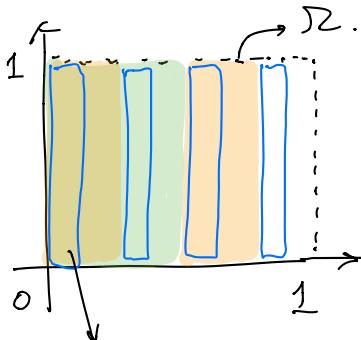

if for any subset $S \subset \{1, 2, \dots, n\}$, $P(\bigcap_{i \in S} A_i) = \prod_{i \in S} P(A_i)$.

Remark. Mutual independence implies pairwise independence.
(any pair is independent)

However, the converse is not true.

(Mutual Independence $\stackrel{\Rightarrow}{\nLeftarrow}$ Pairwise Independence)

Example.

A_1, A_2, A_3

are mutually independent,
and pairwise independent.

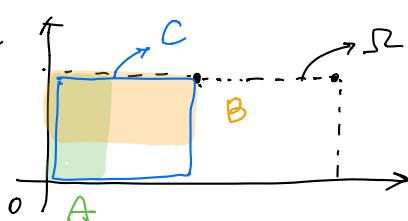

$$P(A_1 \cap A_2 \cap A_3) = \frac{1}{8} = P(A_1)P(A_2)P(A_3) = \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2}$$

iii) Conditional Independence.

A and B are conditionally independent given C

if $P(A \cap B | C) = P(A|C)P(B|C)$ and $P(C) > 0$.

Example

A and B are not independent,
but conditionally independent
given C .

Remark

Independence $\not\Rightarrow$ Conditional Independence.

iv) (Mutual) Independence of an infinite sequence of events

Infinite set of events A_1, A_2, \dots , are (mutually) independent

if for any finite subset $S \subset \{1, 2, \dots\}$, $P(\bigcap_{i \in S} A_i) = \prod_{i \in S} P(A_i)$
→ Avoiding circular definition.

Note Nearly the same compared to ii).

v) Conditional Independence of multiple events.

Finite set of events A_1, A_2, \dots, A_n are conditionally independent given C

if for any finite subset $S \subset \{1, 2, \dots, n\}$,

$$P(\bigcap_{i \in S} A_i | C) = \prod_{i \in S} P(A_i | C) \quad \text{and} \quad P(C) > 0.$$

Prop. Suppose $P(B) > 0$.

Then A, B are independent if and only if $P(A|B) = P(A)$.

$$\text{pf)} (\Rightarrow) P(A \cap B) = P(A)P(B), P(B) > 0 \Rightarrow P(A|B) = \frac{P(A \cap B)}{P(B)} = P(A).$$

$$(\Leftarrow) P(A) = P(A|B) = \frac{P(A \cap B)}{P(B)} \Rightarrow P(A)P(B) = P(A \cap B). \quad \square$$

↳ Implies $P(B) > 0$.

Example $\Omega = \{1, 2, 3, 4\}$. $A = 2^{\Omega}$. $P(k) = \frac{1}{4} \quad \forall k \in \Omega$.

$$A = \{1, 2\}, B = \{1, 3\}, C = \{2, 3\}.$$

i) Are A, B independent?

$$\text{pf)} P(A) \cdot P(B) = \frac{1}{2} \cdot \frac{1}{2} = P(A \cap B) = \frac{1}{4}.$$

$\therefore A$ and B are independent. \square

ii) Are A, B, C pairwise independent?

pf) $P(A) \cdot P(B) = \frac{1}{2} \cdot \frac{1}{2} = P(A \cap B) = \frac{1}{4}$. A and B are independent.

$P(A) \cdot P(C) = \frac{1}{2} \cdot \frac{1}{2} = P(A \cap C) = \frac{1}{4}$. A and C are independent.

$P(B) \cdot P(C) = \frac{1}{2} \cdot \frac{1}{2} = P(B \cap C) = \frac{1}{4}$. B and C are independent.

$\therefore A, B, C$ is pairwise independent. \square

iii) Are A, B, C mutually independent?

pf) $P(A)P(B)P(C) = \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} \neq P(A \cap B \cap C) = 0$.

$\therefore A, B, C$ is not mutually independent. \square

iv) Are A, B conditionally independent given C ?

pf) $P(A \cap B | C) = \frac{P(A \cap B \cap C)}{P(C)} = 0$

$P(A|C)P(B|C) = \frac{P(A \cap C)}{P(C)} \cdot \frac{P(B \cap C)}{P(C)} = \frac{1}{2} \cdot \frac{1}{2} = \frac{1}{4} \neq P(A \cap B | C)$

$\therefore A, B$ are not conditionally independent given C . \square

2.4-5 Three Essential Rules for Probability

Remark. $P(A \cap B) = P(A|B)P(B)$ if $P(B) > 0$.

Thm. Bayes' Rule

$$P(B|A) = \frac{P(A|B)P(B)}{P(A)} \text{ if } P(A) > 0 \text{ and } P(B) > 0.$$

Remark. Bayesian Statistics.

For example, let's say that data we observe are determined by some event A , and probabilistic model with parameters determined by some event B , when we define a probabilistic model, we often find in terms of the probability of seeing a particular data, given some parameter values.

Bayes' rule allows us to invert the conditional probabilities in subsets, that is, if we observe some data, we can infer the probability of parameter values given the data.

Thm. Chain Rule.

If for events A_1, A_2, \dots, A_n and $P(A_1 \cap A_2 \cap \dots \cap A_{n-1}) > 0$,

$$P(A_1 \cap A_2 \cap \dots \cap A_n) = P(A_1) P(A_2 | A_1) P(A_3 | A_1 \cap A_2) \dots P(A_n | A_1 \cap A_2 \cap \dots \cap A_{n-1}).$$

(pf). By mathematical induction.

If $n=2$, $P(A_1 \cap A_2) = P(A_1) P(A_2 | A_1)$,
so the chain rule holds.

Suppose the chain rule holds at $n-1$.

Let $B = A_1 \cap A_2 \cap \dots \cap A_{n-1}$.

$$P(B) = P(A_1) P(A_2 | A_1) \dots P(A_{n-1} | A_1 \cap A_2 \cap \dots \cap A_{n-2}).$$

$$\begin{aligned} P(A_1 \cap A_2 \cap \dots \cap A_n) &= P(B \cap A_n) = P(A_n | B) P(B), \\ &= P(A_1) P(A_2 | A_1) \dots P(A_n | A_1 \cap A_2 \cap \dots \cap A_{n-1}). \end{aligned}$$

So the chain rule holds at n .

Remark. Well-definedness of the chain rule.

$$P(A_1 \cap A_2 \cap \dots \cap A_{n-1}) > 0$$

$\Rightarrow P(A_1) > 0, P(A_1 \cap A_2) > 0, \dots, P(A_1 \cap \dots \cap A_{n-1}) > 0$ by monotonicity.

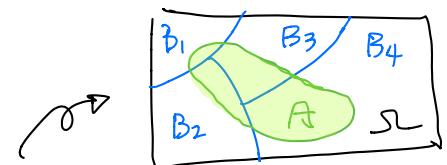

$\Rightarrow P(A_2|A_1), P(A_3|A_1 \cap A_2), \dots, P(A_n|A_1 \cap A_2 \cap \dots \cap A_{n-1})$ is well-defined.

Def. A partition of Ω

is a collection $\{B_i\} \subset 2^\Omega$

finite or countably infinite.
e.g. $\{B_1, B_2, \dots, B_n\}$ or $\{B_1, B_2, \dots\}$.

such that i) $\bigcup_i B_i = \Omega$ and ii) $B_i \cap B_j = \emptyset$ ($i \neq j$)

Thm. Partition Rule.

$$P(A) = \sum_i P(A \cap B_i) \text{ for any partition } \{B_i\} \text{ of } \Omega.$$

$$\text{pf)} A = A \cap \Omega = A \cap \left(\bigcup_i B_i \right) = \bigcup_i (A \cap B_i).$$

countable additivity. $(A \cap B_i) \cap (A \cap B_j) = \emptyset$ ($i \neq j$).

$$P(A) = P\left(\bigcup_i (A \cap B_i)\right) = \sum_i (A \cap B_i)$$

Prop. Conditional probability measure given B .

If $P(B) > 0$, then $Q(A) = P(A|B)$ defines a probability measure Q .

Every "tools" developed for probability measure
can be applied to conditional probability measure.

$$\text{i)} Q(\emptyset) = P(\emptyset|B) = P(\emptyset \cap B) / P(B) = P(\emptyset) / P(B) = 0$$

ii) For pairwise disjoint sets E_1, E_2, \dots, E_n ,

$$\begin{aligned} Q\left(\bigcup_{i=1}^n E_i\right) &= P\left(\bigcup_{i=1}^n E_i | B\right) = P\left(\left(\bigcup_{i=1}^n A_i\right) \cap B\right) / P(B) = P\left(\bigcup_{i=1}^n A_i \cap B\right) / P(B) \\ &= \bigcup_{i=1}^n P(A_i \cap B) / P(B) = \bigcup_{i=1}^n Q(A_i) \end{aligned}$$

$$\text{iii)} Q(\Omega) = P(\Omega | B) = P(\Omega \cap B) / P(B) = P(B) / P(B) = 1$$

\therefore By i), ii), Q is a measure, and by iii), Q is a probability measure.
